ABSTRACT

Background. Minimally invasive lymphadenectomy is progressively emerging as an appealing strategy in patients with vulvar cancer, and at the same time, sentinel node biopsy is currently recognized as standard of care in patients with early-stage disease.

Case presentation. The integration of minimally-invasive approaches and sentinel node biopsy appears as an intriguing horizon, and we present here the first endoscopic sentinel node biopsy using indocyanine green performed in a patient with early-stage vulvar cancer. Twenty-five mg of indocyanine green powder was diluted in 20 ml of injectable solution, and two ml of the solution were injected next to the vulvar lesion. After 10 minutes, the sentinel node was detected using a camera with Karl Storz near infrared system and removed using two ancillary 3 mm trocars. The sentinel node biopsy procedure duration was 25 minutes. Ipsilateral complete endoscopic inguino-femoral lymphadenectomy was then performed. The patient was discharged on post-operative day 1. At frozen section, and final histology one sentinel node was detected, and resulted negative for metastasis. No lymph-nodal metastases were detected in non-sentinel nodes. No surgical complications were observed, and 15 months after surgery the patient was free from disease.

Conclusions. We present the first successful endoscopic inguinal sentinel node biopsy using Indocyanine green. Further studies are needed to clarify the feasibility and safeness of the procedure.

INTRODUCTION

Vulvar cancer is a rare condition affecting older women and accounts for 3-5% of all gynecological cancers, and primary treatment is radical vulvectomy with inguinal nodal staging [1, 2]. However, radical lymphadenectomy is associated with significant morbidities, and in the last decade, a growing attention has been dedicated to the development of sentinel node biopsy (SNB) in women with gynaecological cancer [3-8]. In this context, indocyanine green (ICG) has progressively emerged as the most effec-
Endoscopic inguinal SLN biopsy in vulvar cancer

tive tracer in both endometrial, and cervical cancer given its quick lymphatic diffusion, and favourable economic profile compared to standard radiotracers such as technetium-99 [4-10]. On the other hand, the procedure of SNB has been recently introduced in the clinical practice also in women with early-stage vulvar cancer [11]. At the same time, several reports have demonstrated the feasibility of minimally invasive inguinal lymphadenectomy with significant benefits in term of post-operative complications [12-14]. For these reasons, the combination of inguinal SNB and endoscopic approach appears a promising strategy, giving the opportunity to perform a scar-less procedure with a clear clinical advantage for the patients. However, a surgical description of this challenging surgical technique has never been provided.

CASE PRESENTATION

The presented paper provides a step-by-step description of an endoscopic inguinal SNB using indocyanine green in early-stage vulvar cancer. The procedure has been performed at the Department of Gynecologic Oncology of the University of Palermo. Formal ethical approval was not required for this technical demonstration. Written informed consent to be enrolled, and for personal data to be published in the present article was obtained.

The patient was an eighty-two years old woman with 3 cm vulvar squamous cell carcinoma (Figure 1). Computed Tomography scan and physical exam revealed absence of inguinal lymphadenopathies.

We briefly describe here the surgical steps required to complete the procedure.

First step

As first step, we drew on the patient’s leg the femoral triangle, also identifying the femoral artery (Figure 2).

Second step

A 10-mm trocar for endoscope was placed around 10 cm below the inguinal ligament, furthermore two additional 3-mm trocars were placed externally to the femoral triangle in order to have a direct access to the groin (Figure 3).

Third step

The definition of the surgical field is the further step of the procedure consisting of a careful dissection...
of subcutaneous fatty tissue avoiding as much as possible sealing and cutting thus preserving lymphatic vessels (Figure 4). At the end of this part of the surgery, we were able to identify the two major surgical landmarks: the inguinal ligament ventrally, and the great saphenous vein in the dorsal part of the field (Figure 5).

Fourth step

Then, 25 mg of ICG powder was diluted in 20 ml of water, and 2 ml of the solution were injected next to the vulvar lesion (Figure 6).

Fifth step

After 10 minutes the camera was introduced through the 10-mm trocar, and the sentinel node was detected in the area of superficial inguinal lymph nodes using the endoscopic Karl Storz near infrared system (Figure 7).

Sixth step

Then a careful dissection of the great saphenous vein was performed, which confirmed the ICG uptake only in the detected sentinel node.

Seventh step

Finally, the sentinel node was removed in endobag end submitted to histological examination (Figure 8).
Because of the innovativeness of the procedure, that needs to be validated yet, completion ipsilateral inguino-femoral radical lymphadenectomy was performed as previously described [12-15]. Finally, left radical hemi vulvectomy was performed to complete the surgical procedure.

RESULTS

The SNB procedure duration was 25 minutes, and no significant haematic blood loss were recorded. The patient discharged on post-operative day 1. At frozen section analysis, and at final histology one sentinel node was detected, and resulted negative for metastasis. No lymph-nodal metastases were detected in non-sentinel nodes. No early or late surgical complications were observed and a scarless result was obtained (Figure 9). Fifteen months after surgery the patient was free from disease.

CONCLUSIONS

We present the first case of successful endoscopic inguinal SNB using ICG, a very innovating surgical technique, that could represent a further alternative option for the management of early-stage vulvar cancer. However, our successful demonstration does not support the routine application of the described technique, and further studies are needed to confirm our promising results. The validation of our technique could give the opportunity to perform this minimally invasive technique avoiding a radical lymphadenectomy as suggested by the principal guidelines [8].
